0. Name one of the major responsibilities of a graphics engine.

1. What does `setAnimationFrame` do that a loop and `setInterval` cannot?

2. True or false: coordinate addition and vector addition are equivalent (circle one).

True

False

3. Given coordinates $a = (x, y)$ and $b = (z, w)$, what is the x-component of the vector pointing from a to b?

4. What is the length of this vector?

5. In WebGL, what is the name of the data input into a vertex shader?

6. What do we call data that moves from the vertex to fragment shader?

7. What do we call the data that is constant for both vertex and fragment shaders?

8. What *generally* executes more often (circle one)?

Vertex shader

Fragment shader

9. What is a draw call?

10. What two buffers have we used to render geometry?

11. How are these two buffers related?

12. Enumerate three different render modes.

13. Give three examples of affine transformations.

14. Given the coordinate (x, y, z), what is the corresponding homogeneous coordinate before any other transformations are applied?

15. The **Model Matrix** transforms between what two spaces?

16. The **Projection Matrix** contains two transformations: what are they?

17. Define "clip-space".

18. What six planes define a frustum?
